## Databases and Inventories

## Abstract

**Background:** The use of medicinal plants (MP) is a very common practice among Amazonian communities. Traditional knowledge is a good source of information for planning strategies for the conservation of MP. Here, we identify medicinal species to be prioritized for conservation in communities of riverside dwellers along the Pará River and Marajó Bay, in the Amazon estuary.

**Methods:** We searched the scientific literature of the last 35 years (1985 to 2020) on the use and knowledge of these resources and aspects related to medicinal versatility, forms of collection, parts used, anthropic pressure and origin (cultivation/extractivism) to estimate the indices of Relative Importance (RI), Sensitivity (SI) and Importance Value (IVI) in order to evaluate the priority species for conservation actions.

**Results:** A total of 343 MP was recorded, distributed in 84 botanical families, with Fabaceae standing out. *Socratea exorrhiza* (*paxiúba*), a typical floodplain species, stood out as the most vulnerable to anthropogenic collection and pressure (SI = 0.99). *Carapa guianensis* (*castanha-do-Pará/Brazil nut*) stood out with great versatility regarding its uses (RI = 1.88) and higher importance value (IVI = 2.85).

**Conclusions:** Another 33 species can be considered high priority for conservation in the communities surveyed. Recommendations were suggested for local strategies for sustainable use and management.

**Keywords:** Ethnobotany, Medicinal species, Brazilian Amazon, Amazonian Floodplain Forest, Local Knowledge.

## Background

The use of medicinal plants (MPs) is a very common practice among different peoples and communities in the Amazon. This region is known for its remarkable biological and sociocultural diversity, which is closely linked to a vast body of knowledge held by local populations, particularly regarding natural resources with therapeutic potential (Pedrollo *et al.* 2016, Ellwanger *et al.* 2020). The riverine communities that live in the floodplain forests, along the banks of rivers, channels, and streams, represent one of these social groups that inhabit the estuary formed by the confluence of the Amazon and Tocantins rivers, between the states of Pará and Amapá (Ab'saber 2005). The relationship of riverside dwellers with their environment generates important knowledge about native and introduced MPs in local ecosystems, forming a unique pharmacopeia characteristic of the Amazon estuary (AE) (Amorozo & Gély 1988, Almeida & Jardim 2012, Marques *et al.* 2020).

The AE holds historical, cultural, and ecological significance in the Amazonian context. In pre-colonial times, the region was characterized by rich sociocultural diversity with activities dating back at least 5,000 years BP (before present), including the development of navigation, fishing, and estuarine flora management technologies (Roosevelt 1991, Schaan 2010); centuries later, it became the site of European contact with the Amazon, with intense port and trade activities (Costa 2019). Ecologically, the territory includes the Belém Endemism Center (Almeida e Vieira 2010), considered one of the richest in biodiversity within the Amazon, but also the most threatened due to human activities over recent decades (Hecht 2019, Brandão *et al.* 2022). There are signs of population losses of species that are already considered to be critically endangered in this area (SEMAS 2007, Almeida *et al.* 2014, BRASIL 2022).

Beyond habitat loss and fragmentation due to climate change, pollution, deforestation, mining, or urbanization, the overexploitation of these plant resources can make many MP species rare, threatened, or endangered, posing a challenge to conservation strategies (Howes *et al.* 2020). These aspects need to be considered to provide sustainable alternatives for the exploitation and management of biodiversity in the local context, requiring the identification of medicinal species that are priorities for conservation (Lucena *et al.* 2013).

The interest in integrating local knowledge into conservation efforts is highlighted by the Global Strategy for Plant Conservation (GSPC), which guides the development of public policies aimed at the conservation and sustainable use of genetic resources related to human survival (Target 15 - CBD 2010, Sharrock 2020). In this context, information about plant uses in communities can guide conservation agendas; however, before taking steps to protect and manage these resources, it is necessary to identify the species under the most pressure, whether for medicinal use or other forms of exploitation (Campos & Albuquerque 2021).

Although ethnobotanical research in the AE has contributed to documenting numerous plant species used by riverine communities (Amorozo & Gély 1988, Almeida & Jardim 2012, Santos *et al.* 2019, Marques *et al.* 2020, Santos *et al.* 2020), this dataset has great potential to support new analyses, including those focused on the conservation of plants that are part of the regional pharmacopeia, given that the area is highly impacted by anthropogenic activities (Piratoba *et al.* 2017, Ellwanger *et al.* 2020), therefore, it is important to assess the conservation status of MPs that are valuable to local communities.

The primary objective of this study was to investigate the use of MPs by riverine communities in the Pará River and Marajó Bay region of the AE. This involved compiling information on their uses, the parts of the plant used, preparation methods, and estimating the importance value index. Ultimately, this research aimed to contribute to the development of effective conservation strategies for Amazonian medicinal species.

## Materials and Methods

The study area encompasses the influence zone of the Pará River and Marajó Bay (located between 1°52'50.3"S 49°06'10.9"W upstream and 1°09'9.92"S 48°25'12"W downstream of the Amazon Estuary), which is part of the Amazon estuarine system. This area is influenced by the Amazon and Tocantins-Araguaia hydrographic regions (between the municipalities of Igarapé-Miri and Abaetetuba), the Guajará and Marajó Bays (in the municipalities of Barcarena, Belém, and Ananindeua), and the Western North Atlantic region (Ab'saber 2005, Prestes *et al.* 2020) (Fig. 1).

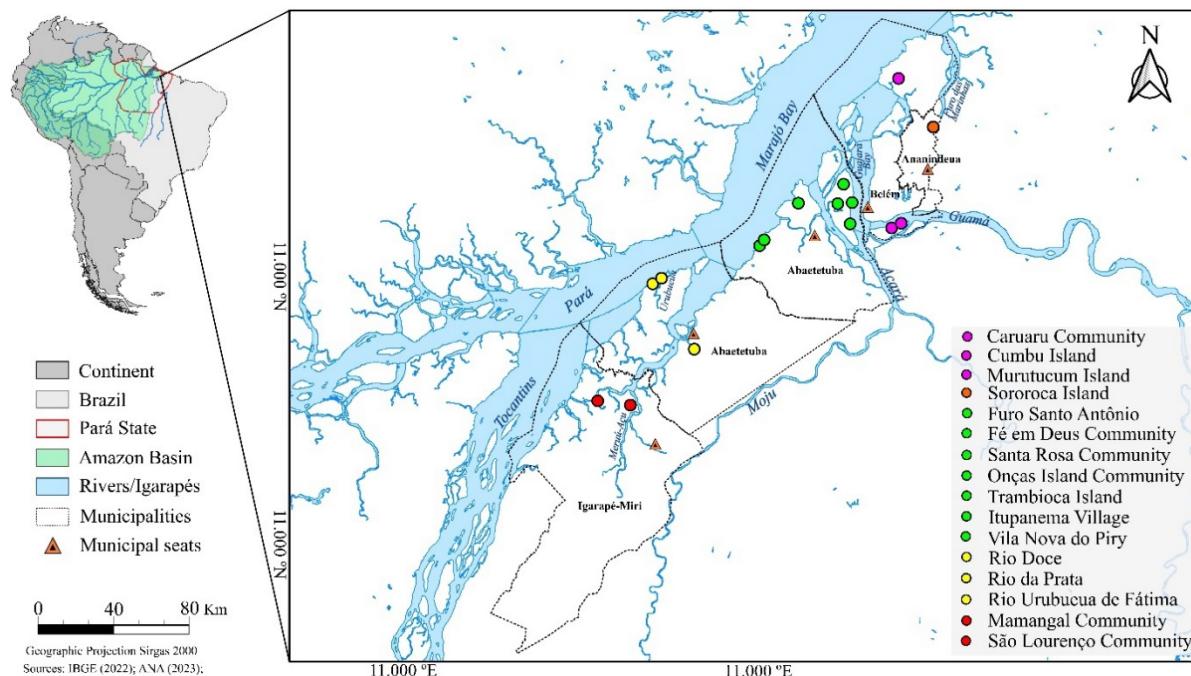

Figure 1. Riverside communities recorded in 19 studies on the use of MP in the AE, Brazil.

The region's climate is hot and humid, with average temperatures ranging between 25-26.7°C, and marked by seasonal rainfall patterns (drier season from August to December, and wetter season from January to July). The vegetation is adapted to flooding conditions caused by tidal flows, with the predominant type being Dense Alluvial Rainforest (IBGE 2012) characterized by the dominance of a few species, such as **andiroba** (*Carapa guianensis* Aubl.), **buriti** (*Mauritia flexuosa* L.f.), **muru-muru** (*Astrocaryum murumuru* Mart.), **pracuúba** (*Mora paraenses* (Ducke) Ducke), **seringueira/rubber tree** (*Hevea brasiliensis* (Willd. ex A.Juss.) Müll.Arg.), **taperebá** (*Spondias mombin* L.), **taxi** (*Tachigalia paniculata* Aubl.), **ucuúba** (*Virola surinamensis* (Rol. ex Rottb.) Warb.) and especially **açaí** (*Euterpe oleracea* Mart.). The region also contains upland rainforests (Dense Rainforest), as well as extensive mangrove ecosystems along the entire length of the Pará River's banks. The AE is subject to anthropogenic activities, leading to high levels of river contamination (Piratoba *et al.* 2017), deforestation (Ellwanger *et al.* 2020), and more recently, the pre-salt oil exploration poses threats to species conservation (Dos Santos *et al.* 2016).

#### Data collection

The data for this research were obtained from articles published between 1985 and 2020 on the use of MPs by various riverine communities within the study area. The year 1985 was chosen as the starting point because it represents the oldest publication found in the consulted databases that still significantly contributes to our current understanding of the subject. This period encompasses both pioneering studies in the field and more recent research, allowing for an analysis of the evolution of knowledge on the topic over the past decades. Relevant literature was retrieved from the Scopus® ([www.scopus.com](http://www.scopus.com)); Scielo® ([www.scielo.br](http://www.scielo.br)); Google Scholar® ([www.scholar.google.com.br](http://www.scholar.google.com.br)) e Web of Science® ([www.webofknowledge.com](http://www.webofknowledge.com)); databases, as well as the Portal Portal de Periódicos da Capes ([www.periodicos.capes.gov.br](http://www.periodicos.capes.gov.br)), Directory of Open Access Journals ([doaj.org/](http://doaj.org/)), Biblioteca Virtual em Saúde ([bvsalud.org/](http://bvsalud.org/)) and the Digital Repository of the Emílio Goeldi Museum ([repositorio.museu-goeldi.br](http://repositorio.museu-goeldi.br)). Keyword combinations in Portuguese, English, and Spanish were used: "Ethnobotany," "medicinal plants," "medicinal use," "riverine communities," "Pará," and "Brazil." An additional search was conducted on the Lattes® Platform ([buscataltexual.cnpq.br/buscatextual/busca.do](http://buscataltexual.cnpq.br/buscatextual/busca.do)) using the established keywords, and references from each selected article were used as complementary sources. The *inclusion criteria* were studies whose research area was located entirely or predominantly in the study area; those addressing knowledge and/or use of MPs by riverine communities; adopting methodologies characteristic of ethnobotanical research (e.g., interviews and participant observation); published within the established period and fully available in the databases searched. Gray literature, bibliographic reviews, checklists, and floristic surveys without the involvement of riverine communities were not selected. Articles that only included vernacular species names were also excluded.

### Screening and selection

The screening process involved the removal of duplicate documents, followed by an analysis of the titles and abstracts of the articles, eliminating those that were not aligned with the theme and objectives of this research. The articles selected in the previous phase were read in full and evaluated according to the inclusion and exclusion criteria. Nineteen studies were then selected. The process of retrieving, screening, and selecting the articles is summarized below (Fig. 2).

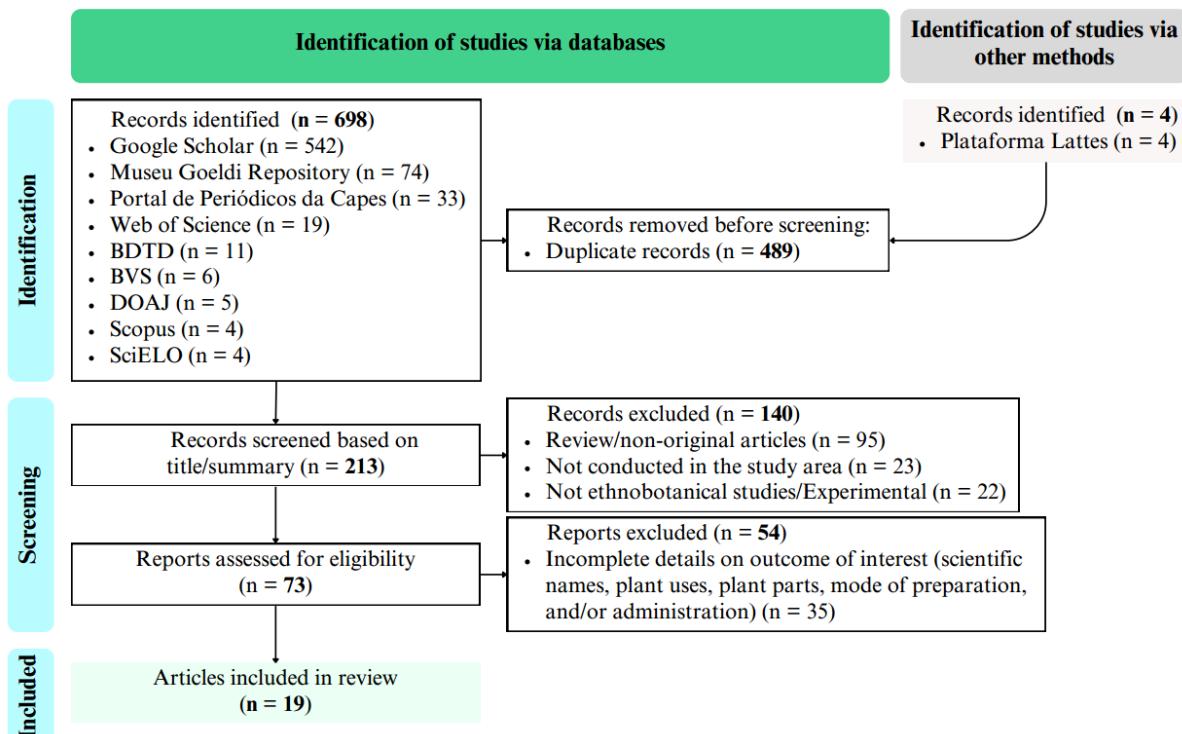

Figure 2. Study flowchart showing the process of screening and selecting articles.

### Data Organization and Analysis

The selected information was organized into a database according to the following categories: study identification, scientific and vernacular names; botanical family; habit (life form); threat status (CNCFlora/IUCN); origin (native to the Amazon biome/exotic); acquisition (cultivated/extracted); method(s) of preparation/application; part(s) used; therapeutic indications; other uses; and disease category(ies). To supplement this information, we consulted the MGetno collection and the database of the Ethnobotany and Economic Botany Laboratory – Botany Coordination of the Emílio Goeldi Museum (COBOT/MPEG), a reference collection for incorporated specimens, raw materials, and plant artifacts traditionally used in the Amazon region (Melo *et al.* 2019).

The medicinal plants were grouped into 15 nosological categories based on the International Classification of Primary Care – ICPC-2 (WONCA 2005). Information on species used for magical and/or ritualistic purposes or symptoms and manifestations without a scientifically established cause (in official medicine) was grouped into an extra category called "Cultural Diseases" (Amorozo 2002), which encompasses emic categories such as "evil eye," "quebranto," "panema," "mãe do corpo," among others.

The life forms and scientific names were updated according to the Flora of Brazil ([floradobrasil.jbrj.gov.br](http://floradobrasil.jbrj.gov.br)) and SpeciesLink ([specieslink.net](http://specieslink.net)). During this process, the origin of the species was also verified, with native species being those naturally found in the Amazon region and introduced/cultivated/exotic species being those from other regions of the world. The list of medicinal species was organized following the APG IV system.

The conservation status of the species was determined by consulting the lists from the National Center for Plant Conservation – CNCFlora ([cncflora.jbrj.gov.br](http://cncflora.jbrj.gov.br)); the Red Book of the Flora of Brazil by Martinelli and Moraes (2013); the List of Threatened Plant Species of the State of Pará (SEMAS 2007); the Official List of Threatened Plant Species of Brazil (BRASIL 2022), and the International Union for Conservation of Nature – IUCN ([iucnredlist.org](http://iucnredlist.org)).

### **Approach for Prioritizing Species**

The Importance Value Index (IVI) proposed by Dhar *et al.* (2000), with adaptations from Melo *et al.* (2009), was used to categorize medicinal species based on conservation priorities. The IVI considers the diversity of uses of the species along with their conservation attributes, calculated by summing two other indices: Relative Importance (RI) and Sensitivity Index (SI), given by the formula:  $IVI = RI + SI$ . RI assesses the importance of different species based on their versatility, without considering the number of people who cited their uses. It is calculated using the formula:  $RI = NSC + NP$ . NSC is the ratio between the number of body systems treated by a species (NSCE) and the total number of body systems treated by the most versatile species (NSCEV), given by the formula:  $NSC = NSCE/NSCEV$ . NP refers to the number of properties attributed to a particular species (NPE), divided by the total number of properties attributed to the most versatile species (NPEV), calculated as:  $NP = NPE/NPEV$ . SI ranks the vulnerability of medicinal plants, considering the method of acquisition and anthropogenic pressure on exploited resources, using the formula:  $SI = [(SR \times NR) / \sum(SR \times NR)] \times 100$ . SR is the Sensitivity Rank, and NR is the Naturalness Rank. SR combines attributes such as the collection method (destructive or non-destructive) and the degree of anthropogenic pressure (high, very high, or moderate), assigning sensitivity scores from 1 to 6. Collection is considered destructive when it involves harvesting entire plants, roots, and/or rhizomes, or the complete removal of bark. SR also considers other usage categories, using the following criteria: moderate anthropogenic pressure – when only medicinal use is noted; high anthropogenic pressure – when medicinal use is associated with fuel or construction categories; and very high anthropogenic pressure – when medicinal use is combined with two or more categories of use. NR is determined according to the method of acquisition of medicinal species, with the following scores: 3 – for species obtained exclusively through extraction (natural/wild); 2 – obtained through both extraction and cultivation; and 1 – for species obtained solely through cultivation (Dhar *et al.* 2000). Based on the IVI, endemic Amazonian species obtained through extraction were highlighted to prioritize them.

## **Results**

### **Diversity of medicinal plants, habit, parts used, methods of preparation and application**

In this investigation, 19 original studies were selected (Table 1) and 657 records of specimens cited in these studies were obtained, corresponding to 343 MPs.

Table 1. Checklist of selected articles on MP used by riverine communities in AE. Met. (research methodology); E. (interview); LI. (free list); Tr. (guided tour); Op. (participant observation); On. (non-participant observation); Ef. (phytochemical study); In. (non-specific induction); Es. (semi-structured interview); Qe. (structured questionnaire); Qs. (semi-structured questionnaire); Collab. The identified species belong to 84 botanical families, with Fabaceae (30 spp.), Lamiaceae (26 species), and Asteraceae (15 species) standing out. *Plectranthus* (6 spp.) was the most representative genus among the 238 identified. The most frequently cited species was *Carapa guianensis* (12 citations), followed by *Euterpe oleracea* (11) e *Eleutherine bulbosa* (Mill.) Urb. (10). Most of these species are native plants (61.2%), with the majority being non-endemic to Brazil (57.4%), followed by those endemic to the Brazilian Amazon (2.3%); the data also revealed endemic species from other biomes (1.5%) such as the Caatinga, Cerrado, Atlantic Forest, and Pantanal.

Among the MPs, herbaceous plants (39.7%) were predominant, and most of the herbal remedies were prepared from leaves (44%). The most common preparation method was tea (58.9%), while baths (69.7%) were the most notable among the modes of application (Fig. 3).

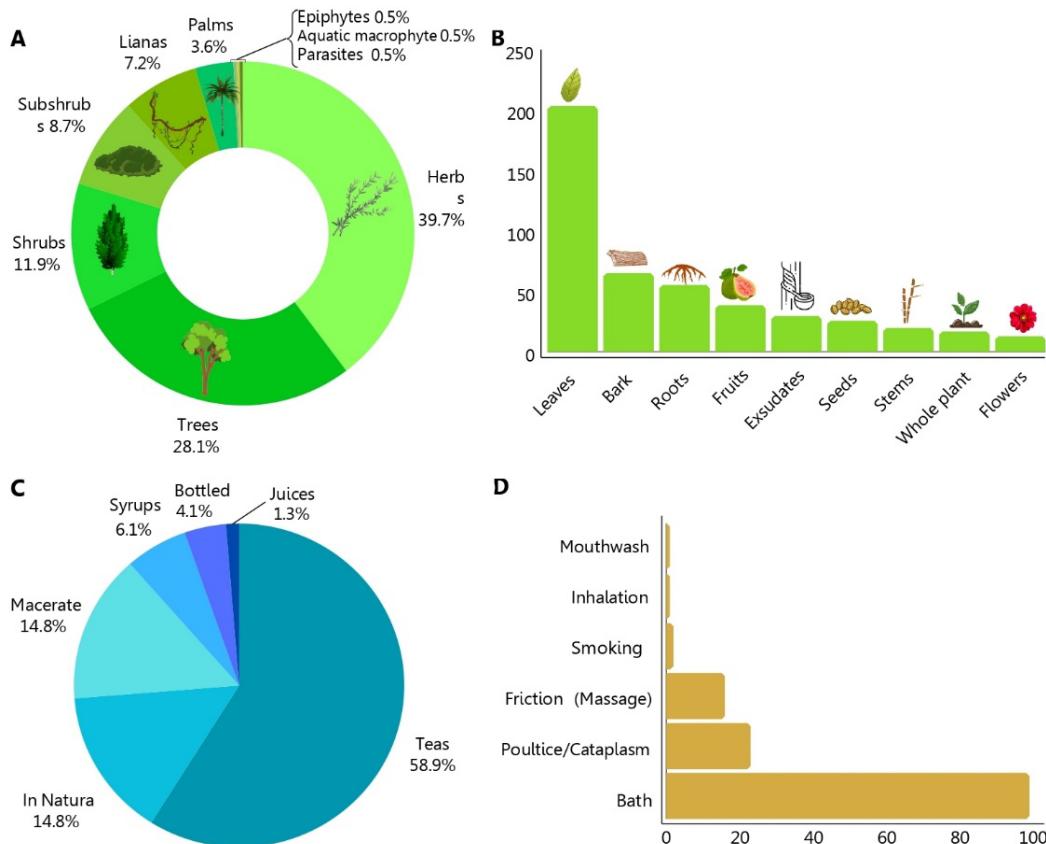

Figure 3. Characteristics of MP used in the study area. (A) Growth form habits represented in the doughnut chart; (B) Plant parts used represented in the bar graph; (C) Preparation methods in the pie chart; and (D) Application methods, represented in the bar chart.

#### Diseases Treated in the Study Area

The identified species are used to treat 1,175 diseases, signs, or symptoms, which were grouped into 15 categories from the International Classification of Primary Care (ICPC-2) and one additional category for 'Cultural Diseases' (Table 3). The "D – Digestive" category was the most represented, with diarrhea being the most cited symptom within this group. Following that, the "A – General and Unspecified" category highlighted fever as the most representative symptom. \*Insert which cultural diseases were identified. Frequency of the most cited diseases in each category (ICPC-2). The "evil eye" stood out among the category of cultural illnesses.

#### Conservation Priorities for Medicinal Species

According to the analysis, 22 medicinal species had a Relative Importance (RI) greater than one, indicating significant versatility in their medicinal applications, with some species being used for up to eight body systems. For example, *Carapa guianensis* (*andiroba*) had the highest number of therapeutic uses (26) and showed the maximum RI value (1.88).

Regarding the Sensitivity Index (SI), extraction methods and anthropogenic pressures associated with the way the species are obtained were evaluated, represented by Sensitivity Rankings (SR) and Naturalness Rankings (NR), respectively. In terms

of SR, non-destructive harvesting was reported for 56% of taxa (194 spp.), while destructive harvesting was cited for 44% (149 spp.). Among destructively harvested species, trees were predominant (39.7%, 58 spp.), followed by herbs (30.8%, 45 spp.). The number of species experiencing high and very high anthropogenic pressure was highest among trees (42%, 40 spp.), followed by herbs (26%, 25 spp.) (Fig. 4).

Table 3. Frequency of most cited diseases in each category (ICPC-2).

Categories	Frequency (%)	Diseases/Symptoms cited in the category	most	N. species per category
D - Digestive	21,93	Diarrhea	144

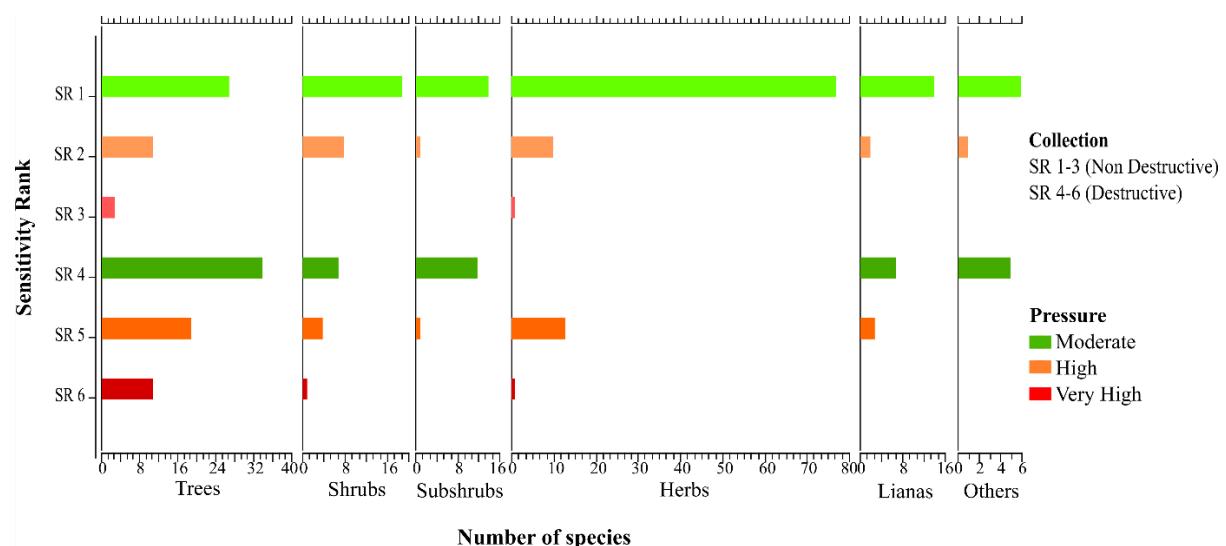

Figure 4. Sensitivity Rank (SR) frequency for different life forms found in riverine communities of the AE, Pará River, Brazil.

Regarding NR, 128 species are obtained through extractivism (NR3 = 37.3%), 41 species are both cultivated and harvested from the wild (NR2 = 12%), and 174 species are cultivated (NR1 = 50.7%), mainly in home gardens. When relating NR to plant habits, herbs were predominant among plants obtained exclusively through cultivation (NR1 – 95 spp.), while trees were harvested through both cultivation and extractivism (NR2 – 8 spp.) and exclusively via extractivism (NR3 – 69 spp.) (Fig. 5), such as the fruit trees *Garcinia macrophylla* Mart. (**bacuri**), *S. mombin* (**tapereba**), *Bertholletia excelsa* Bonpl. (**castanha-do-Pará/Brazil nut**) and *Endopleura uchi* (Huber) Cuatrec. (**uxi**).

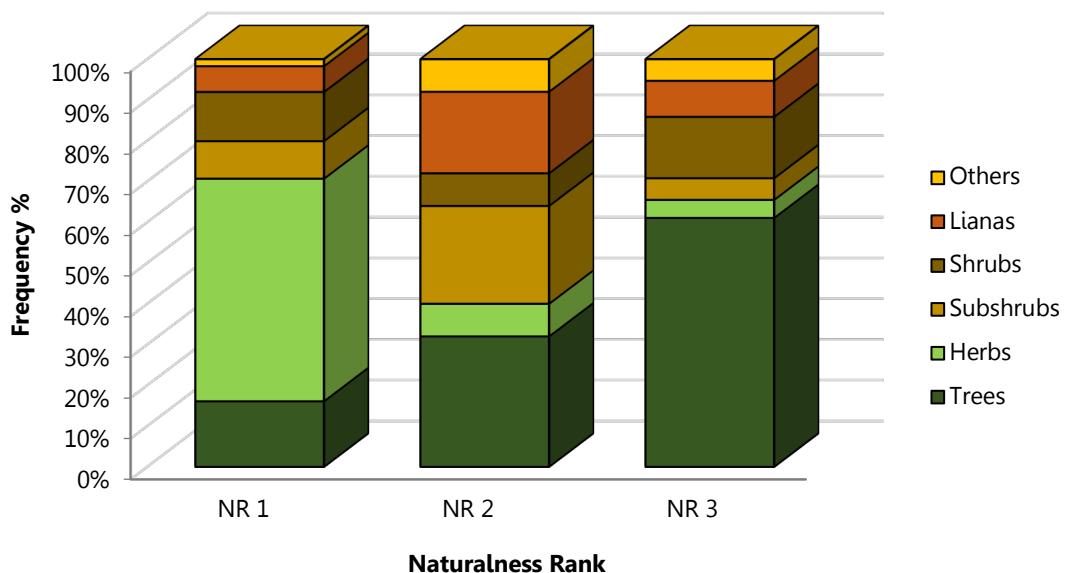

Figure 5. Naturalness Rank (NR) frequency for different habits found in the AE, Pará River, Brazil. NR 1 – plants obtained from cultivation; NR 2 – plants acquired from both extractivism and cultivation; NR 3 – plants harvested exclusively through extractivism.

Regarding the Sensitivity Index (SI), no species in this study had a value equal to or greater than one ( $SI \geq 1$ ), likely due to the large amount of data, which led to highly fragmented results. The highest SI value was 0.99, attributed to *Socratea exorrhiza* (Mart.) H.Wendl. (**paxiúba**). Other more sensitive species had SI values of 0.97, including: *B. excelsa* (**castanha-do-Pará/Brazil nut**), *Calophyllum brasiliense* Cambess. (**jacareúba**), *C. guianensis* (**andiroba**), *Erythrina* sp. (**açacu-rana**), *Genipa americana* L. (**genipapo**), *Lecythis pisonis* Cambess. (**sapucaia**), *Macrolobium angustifolium* (Benth.) R.S.Cowan (**ipê-da-várzea**), *M. flexuosa* (**miriti**), *Symphonia globulifera* L.f. (**anani**), *V. surinamensis* (**ucuúba**) and *Vismia cayennensis* (Jacq.) Pers. (**lacre-branco**).

In terms of the Importance Value Index (IVI), 74 species had values above one, with *C. guianensis* standing out (IVI = 2.85). Notably, 35 species were identified with high conservation priority, most of which are trees (Table 4).

Tabela 4. Species with high conservation priority in the study area. (T) tree; (Sh) shrub; (P) palm tree; (Ss) subshrub; (S) spontaneous; (C) cultivated; <sup>a</sup> Endemic species in the Brazilian Amazon.

## Discussion

The studies identified highlight the sociocultural importance of MPs in the riverside communities of the EA. They showed a higher species richness for the Fabaceae botanical family, a predominance corroborated by studies conducted in other non-estuarine Amazonian riverside communities (Pedrollo *et al.* 2016). This family includes many cosmopolitan medicinal species with significant economic interest and phytochemical characteristics that make them highly versatile. They rank among the top ten most species-rich families in all Brazilian biomes, particularly in the Amazon (BFG 2015). The use of these species may be related to their abundance in local vegetation or their cultivation near homes for multiple purposes—such as food, artisanal products, technology, construction, fuel, and ornamentation—besides their medicinal use in the studied communities. The most frequently mentioned species for treating illnesses were *andiroba* (*C. guianensis*) and *açaí* (*E. oleracea*), both widely used by the riverside dwellers (Sousa *et al.* 2019), with growing value chains in the market, currently reaching significant production scales in the pharmaceutical, cosmetic, and food industries (Shanley & Medina 2005, Costa *et al.* 2021).

A higher proportion of native species in the riverside communities' pharmacopoeias was expected, as traditional communities develop socio-ecological systems closely tied to areas of native vegetation, reducing the cost of accessing these plant resources (Medeiros et al. 2017). Moreover, these are resourcing whose use is derived from ancestral knowledge, based on native plants managed in their territories. Notably, there is a tradition of plant exchange (especially medicinal, ornamental, and edible) in the study area, which promotes increased diversity of both native and exotic species in riverside gardens. Exotic species (from Europe, Asia, and Africa) were observed in all the selected studies, indicating a strong introduction of these plants into the Amazonian estuarine pharmacopoeia, aligning with the observations of Bennet & Prance (2000). According to these authors, some of these plants were initially introduced as food or ornamental species, and after experimentation to confirm therapeutic effects, they were incorporated into local pharmacopoeias. Alencar et al. (2010) argue that this happens mainly to fill gaps not covered by native plants, or to diversify and expand the range of local medicinal plants, rather than simply representing acculturative processes or knowledge erosion. The intercultural exchanges with African and European peoples were relevant to the diversity of introduced species in this estuary since historically, this region was a hub for the flow of plants, which centuries later remain valued elements in regional pharmacopoeias (Costa 2019).

The identified medicinal plants are mostly herbs, predominantly cultivated or fast-growing and spontaneous in fields and along riverbanks near homes. Generally, these are plants that are easy to cultivate, harvest, and propagate, making them convenient for use (Voeks & Leony 2004). The preference for leaves in medicinal preparations may be related to their year-round availability and their ability to accumulate bioactive compounds, useful in many preparations like teas and baths, which are widely used by other ethnic groups (Wagner et al. 2013). These findings align with trends observed in other regions (Bieski et al. 2015, Rodrigues et al. 2021).

Most of the plant species treat disorders related to the digestive, general, and non-specific categories (fever, pain, and headache), respiratory and skin problems—conditions that are likely more common in the study area, particularly gastrointestinal diseases and symptoms, which have been documented in many studies conducted with various human groups in the Amazon and around the world (Rehecho et al. 2011, Bieski et al. 2015, Pedrollo et al. 2016, Miara et al. 2020). In Pará state, diarrhea (or Acute Diarrheal Disease - ADD) is one of the leading causes of morbidity and mortality, particularly affecting children under one year of age (Sousa et al. 2020). The high frequency of mentions in the 'D - Digestive' category (with diarrhea being the main symptom) is likely related to the communities' dependence on river water for household activities and consumption. These communities lack infrastructure and basic sanitation services, which contributes to contamination, the proliferation of vectors, and a range of waterborne diseases such as amebiasis, giardiasis, cholera, typhoid fever, hepatitis A, salmonellosis, and others (Souza et al. 2012). The seeds of **jucá** (*Libidibia ferrea* (Mart. ex Tul.) L.P.Queiroz), **açaizeiro** roots (*E. oleraceae*), **marupazinho** pseudobulbs (*E. bulbosa*), barks of **sucuúba** (*Himatanthus articulatus* (Vahl) Woodson) and **verônica** (*Dalbergia monetária* L.f.), the leaves of **goiabeira/guava** (*Psidium guajava* L.), **elixir paregórico** (*Piper callosum*) and **pariri** (*Fridericia chica*) are some of the most frequently used remedies for treating diarrhea in the study area.

Although not among the most representative categories, 'Cultural Diseases' play a central role in the traditional medicine of many Amazonian communities. In this category, diseases were reported as having non-natural causes, recognized within the communities' culture, including the evil eye (11 mentions), *panema* (5), *quebranto* (4), *olhado-de-bicho* (3), and *mãe-do-corpo* (2). Some studies have reported the occurrence of these diseases in the Amazon region (Bieski et al. 2015, Pedrollo et al. 2016), and they are part of the reality for many other rural populations worldwide.

Regarding the Relative Importance Index (RI), the high values for *C. guianensis*, *H. articulatus*, *Cnidoscolus urens* (L.) Arthur, *Protium heptaphyllum* (Aubl.) Marchand, *D. monetaria*, *Senna alata* (L.) Roxb., and *L. ferrea* may indicate the actual effectiveness of these plants in curing and treating the diseases reported by the communities, as this index is based on the body systems with the highest number of indications (mainly the gastrointestinal system). The number of properties for each species was considered, and thus, this index also tends to identify the most versatile species, highlighting them for future pharmacological studies (Lucena et al. 2013).

Unsustainable practices have a significant impact on MPs populations. The extraction of bark, roots, and whole plants is highly destructive, while the use of leaves, flowers, fruits, and seeds presents medium or low risk to target species (Teklehaymanot & Giday 2007). Even though destructive harvesting practices were observed less frequently in this study, they deserve special attention for management and sustainable use, and these practices should be discussed and established according to the interests of each community (Campos & Albuquerque 2021). When linking harvesting methods (NR) to different levels of anthropic pressure (SR), trees generally exhibit greater sensitivity than other life forms, primarily due to

the extraction of wood for construction and fuel use. *S. exorrhiza* (**paxiúba**) was the most sensitive species according to the SI. This native species is spontaneously found in the communities, with its roots harvested destructively for medicinal preparations. It is also used in house and bridge construction, as well as in crafts and ornamentation, leading to extremely high anthropic pressure, as these activities contribute to the species' increased sensitivity in these riverside environments (Kikuchi & Callado 2021).

Concerning the Importance Value Index (IVI), most of the priority species for conservation are harvested exclusively through extractivism, mainly for their bark, a practice that can compromise the survival of individuals (Khan *et al.* 2013). The high IVI values attributed to species in this group indicate that they require special attention and conservation efforts. The species highlighted in this group are wild/spontaneous and harvested destructively, either by removing their perennial structures (bark, roots, rhizomes, or tubers) or the entire plant, practices that could lead to local extinction, including species currently considered abundant (Rivers *et al.* 2022). Recognizing the importance of MPs and identifying those requiring priority conservation attention can assist communities in taking steps towards the rational use of these resources, especially when exploitation poses risks to species' survival (Campos & Albuquerque 2021).

Regarding conservation status, all species at risk of extinction are trees and have multiple uses beyond medicinal, with high economic value as timber and non-timber forest products. It is worth noting that of the 210 native species, 178 have not been assessed for conservation status. Many of these species are shared with other countries in the International Amazon, and only Brazilian native and endemic species have been evaluated by the National Center for Flora Conservation (CNCFlora 2023). Therefore, a particular approach is recommended for Amazonian species under some form of usage pressure that have not yet been adequately addressed by conservation bodies.

#### ***Recommendations and conservation strategies***

There should be continuity in the documentation of MP use in other riverside communities of the EA to study new uses, preparations, and/or extractions, or even the inclusion of potential new species. Besides guiding conservation and sustainable use actions among community members, local research groups should enhance research on species taxonomy, ecology, and, especially, ethnopharmacological studies to evaluate these medicinal resources. Future research in the region should also assess MP populations derived from extractives and identify user perceptions regarding the main threats to species; these measures should be fundamental to conservation planning.

As alternatives that can be put into practice in riverside communities, it is suggested that, where possible, potential species of medicinal equivalence be used to replace MPs with high IVI. Examples of plants collected in a non-destructive way and with less anthropogenic pressure in riverside communities include: *Ayapana triplinervis* (M.Vahl) R.M.King & H.Rob. (**japana-roxa**), *Bacopa scopariooides* (Cham. & Schltl.) Scatigna (**pataqueira**), *Hyptis sp. nov.* (**salva-do-marajó**), *Eugenia biflora* (L.) DC. (**pedra-hume-caá**), *Gustavia augusta* L. (**geniparana**), *Jatropha gossypiifolia* L. (**pião-roxo**), *Justicia pectoralis* Jacq. (**abre-caminho**), *Mikania parvifolia* Baker (**cipó-caatinga**), *Myrcia bracteata* (Rich.) DC. (**murta-cabeluda**), *Parahancornia fasciculata* (Poir.) Benoit (**Amapá**), *Pilea microphylla* (L.) Liebm. (**cama-do-menino-Deus**) and *Uncaria tomentosa* (Willd. ex Roem. & Schult.) DC. (**unha-de-gato**). These plants have medicinal indications that correspond to the main diseases treated in the communities, such as diarrhea, fever, flu, rheumatism, urinary problems and problems of the female genital system, and can reduce or minimize the use of the species under pressure. Replacing the harvested parts, for example the bark or roots with the leaves of the same plant, can satisfy the need for more sustainable collection; it is also recommended to increase the time intervals between collections so that there is adequate regeneration of the managed specimen; the propagation of medicinal species and the establishment of nurseries in backyards or around communities and agroforestry systems (ex situ conservation) can be a measure to reduce the pressure on resources obtained exclusively through extraction (Khan *et al.* 2013), which is also in line with the GSPC (Sharrock 2020); Implementing collaborative monitoring processes of the local flora can help assess the availability of species in high demand and facilitate adaptation to lower impact conditions (Sobral *et al.* 2017). Most of the species presented in this study originate from native populations, so assessing the impacts of (destructive) extraction and associated pressure, as well as implementing sustainable management actions precisely in the places where these plants are collected, is the most effective way of conserving these resources. For this reason, decisions about which species should be prioritized in conservation strategies need to be linked to local populations so that actions can be implemented that will have a greater chance of success, guaranteeing more participatory and democratic management of biodiversity (Campos & Albuquerque 2021).

## Conclusion

Riverine communities in the EA are knowledgeable about the identities and applications of medicinal species found in their region. Many riverine residents in this estuary still rely on plants, at least for the treatment of basic human ailments such as diarrhea, fever, flu, skin infections, rheumatism, and sexually transmitted infections. The IVI presents medicinal species with high conservation priority, most of which are trees. There is a need to intensify conservation efforts, especially for endemic native species of the Brazilian Amazon such as: *L. pisonis*, *E. uchi*, *M. paraensis*, *Tabernaemontana angulata* Mart. ex Müll.Arg. and *Vouacapoua americana* Aubl. Therefore, more research is needed focusing on the conservation priorities of medicinal plants in the EA, since this is a pioneering study based on secondary data from ethnobotanical studies available in the main scientific databases. Studies with this approach need to be encouraged, especially to build a network of information that helps in understanding the diversity of medicinal flora, and identify threats to species, as well as proposed management forms suitable to the interests of the users of these resources.

## Declarations

**List of abbreviations:** MPs – Medicinal Plants; AE – Amazon Estuary; GSPC – Global Strategy for Plant Conservation

**Ethics approval and consent to participate:** Not applicable

**Consent for publication:** Not applicable

**Availability of data and materials:** No datasets have been deposited in public repositories.

**Competing interests:** Authors declare no conflict of interest.

**Funding:** This study did receive fundings of Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for a master's scholarship (Code 001).

**Author contributions:**

WPGM considerably contributed to the literature survey, data collection, map making, analyzed, and wrote the manuscript. MRCF and PGCL supervised in conceptualization, research design, statistical analysis, critical evaluation, helping with discussions, editing, and moderation of the manuscript.
